Misconceptions about Valuation

- Myth 1: A valuation is an objective search for “true” value
  - Truth 1.1: All valuations are biased. The only questions are how much and in which direction.
  - Truth 1.2: The direction and magnitude of the bias in your valuation is directly proportional to who pays you and how much you are paid.

- Myth 2: A good valuation provides a precise estimate of value
  - Truth 2.1: There are no precise valuations
  - Truth 2.2: The payoff to valuation is greatest when valuation is least precise.

- Myth 3: The more quantitative a model, the better the valuation
  - Truth 3.1: One’s understanding of a valuation model is inversely proportional to the number of inputs required for the model.
  - Truth 3.2: Simpler valuation models do much better than complex ones.
Approaches to Valuation

- **Discounted cashflow valuation**, relates the value of an asset to the present value of expected future cashflows on that asset.

- **Relative valuation**, estimates the value of an asset by looking at the pricing of 'comparable' assets relative to a common variable like earnings, cashflows, book value or sales.

- **Contingent claim valuation**, uses option pricing models to measure the value of assets that share option characteristics.
Discounted Cash Flow Valuation

- **What is it**: In discounted cash flow valuation, the value of an asset is the present value of the expected cash flows on the asset.
- **Philosophical Basis**: Every asset has an intrinsic value that can be estimated, based upon its characteristics in terms of cash flows, growth and risk.
- **Information Needed**: To use discounted cash flow valuation, you need
  - to estimate the *life of the asset*
  - to estimate the *cash flows* during the life of the asset
  - to estimate the *discount rate* to apply to these cash flows to get present value
- **Market Inefficiency**: Markets are assumed to make mistakes in pricing assets across time, and are assumed to correct themselves over time, as new information comes out about assets.
### DCF Choices: Equity Valuation versus Firm Valuation

**Firm Valuation:** Value the entire business

**Equity valuation:** Value just the equity claim in the business
The Drivers of Value…

Current Cashflows
These are the cash flows from existing investments, net of any reinvestment needed to sustain future growth. They can be computed before debt cashflows (to the firm) or after debt cashflows (to equity investors).

Growth from new investments
Growth created by making new investments; function of amount and quality of investments

Efficiency Growth
Growth generated by using existing assets better

Expected Growth during high growth period

Length of the high growth period
Since value creating growth requires excess returns, this is a function of
- Magnitude of competitive advantages
- Sustainability of competitive advantages

Cost of financing (debt or capital) to apply to discounting cashflows
Determined by
- Operating risk of the company
- Default risk of the company
- Mix of debt and equity used in financing

Terminal Value of firm (equity)
Stable growth firm, with no or very limited excess returns
DISCOUNTED CASHFLOW VALUATION

I. Measure earnings right..

- Update
  - Trailing Earnings
  - Unofficial numbers

- Normalize Earnings

- Cleanse operating items of
  - Financial Expenses
  - Capital Expenses
  - Non-recurring expenses

- Operating leases
  - Convert into debt
  - Adjust operating income

- R&D Expenses
  - Convert into asset
  - Adjust operating income

Measuring Earnings

Update
  - Trailing Earnings
  - Unofficial numbers
Operating Leases at Amgen in 2007

Amgen has lease commitments and its cost of debt (based on its A rating) is 5.63%.

<table>
<thead>
<tr>
<th>Year</th>
<th>Commitment</th>
<th>Present Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>$96.00</td>
<td>$90.88</td>

Value of Research Asset = $10,112.80 + $1,149.90

Adjusted Operating Income = $5,120 + 3,366 - 1,150 = $7,336 million
II. Get the big picture (not the accounting one) when it comes to cap ex and working capital

- Capital expenditures should include
  - Research and development expenses, once they have been re-categorized as capital expenses.
  - Acquisitions of other firms, whether paid for with cash or stock.

- Working capital should be defined not as the difference between current assets and current liabilities but as the difference between non-cash current assets and non-debt current liabilities.

- On both items, start with what the company did in the most recent year but do look at the company’s history and at industry averages.
Amgen’s Net Capital Expenditures

- If we define capital expenditures broadly to include R&D and acquisitions:
  
  Accounting Capital Expenditures = $1,218 million
  - Accounting Depreciation = $ 963 million
  Accounting Net Cap Ex = $ 255 million
  Net R&D Cap Ex = (3366-1150) = $2,216 million
  Acquisitions in 2006 = $3,975 million
  Total Net Capital Expenditures = $ 6,443 million

- Acquisitions have been a volatile item. Amgen was quiet on the acquisition front in 2004 and 2005 and had a significant acquisition in 2003.
III. Betas do not come from regressions...
Carry much noise…
And cannot be trusted even when they look good...
Bottom-up Betas

Step 1: Find the business or businesses that your firm operates in.

Step 2: Find publicly traded firms in each of these businesses and obtain their regression betas. Compute the simple average across these regression betas to arrive at an average beta for these publicly traded firms. Unlever this average beta using the average debt to equity ratio across the publicly traded firms in the sample. Unlevered beta for business = Average beta across publicly traded firms / (1 + (1-t) (Average D/E ratio across firms))

Step 3: Estimate how much value your firm derives from each of the different businesses it is in.

Step 4: Compute a weighted average of the unlevered betas of the different businesses (from step 2) using the weights from step 3. Bottom-up Unlevered beta for your firm = Weighted average of the unlevered betas of the individual business

Step 5: Compute a levered beta (equity beta) for your firm, using the market debt to equity ratio for your firm. Levered bottom-up beta = Unlevered beta (1+ (1-t) (Debt/Equity))

Possible Refinements

If you can, adjust this beta for differences between your firm and the comparable firms on operating leverage and product characteristics.

While revenues or operating income are often used as weights, it is better to try to estimate the value of each business.

If you expect the business mix of your firm to change over time, you can change the weights on a year-to-year basis.

If you expect your debt to equity ratio to change over time, the levered beta will change over time.
Two examples…

- **Amgen**
  - The unlevered beta for pharmaceutical firms is 1.59. Using Amgen’s debt to equity ratio of 11%, the bottom up beta for Amgen is
  - Bottom-up Beta = $1.59 \times (1 + (1-.35)(.11)) = 1.73$

- **Hyundai Heavy**

<tr>
<td>1999-2008</td>
<td>-2.53%</td>
<td>-6.26%</td>
</tr>
<tr>
<td></td>
<td>(6.36%)</td>
<td>(8.85%)</td>
</tr>
</tbody>
</table>

- An alternative is to back out the premium from market prices:

In 2008, the actual cash returned to stockholders was 68.72. However, there was a 41% dropoff in buybacks in Q4. We reduced the total buybacks for the year by that amount.

Analysts expect earnings to grow 4% a year for the next 5 years. We will assume that dividends & buybacks will keep pace.

Last year’s cashflow (52.58) growing at 4% a year

<p>| | | | | |</p>

Implied Premiums in the US

Implied Premium for US Equity Market
The Anatomy of a Crisis: Implied ERP from September 12, 2008 to January 1, 2009

- Level of the Index = 1825
- FCFE on the Index = 3.75% (Estimated FCFE for companies in index as % of market value of equity)

Other parameters
- Riskfree Rate = 5% (Won)
- Expected Growth (in Won)
  - Next 5 years = 7.5% (Used expected growth rate in Earnings)
  - After year 5 = 5%

Solving for the expected return:
- Expected return on Equity = 9.39%
- Implied Equity premium = 9.39% - 5% = 4.39%

Effect on valuation
- Hyundai’s value @ historical premium (4%) + country (1.2%) : 350,000 Wn /share
- Hyundai’s value @ implied premium: 352,000 Wn/ share
V. There is a downside to globalization…

- Emerging markets offer growth opportunities but they are also riskier. If we want to count the growth, we have to also consider the risk.
- Consider, for example, South Korea as a country. In mid-2008, Korea was rated A2, with a default spread of 0.80%.
  - To estimate the country equity risk premium, we scaled up the default spread to reflect the additional risk in equities.
    - Standard Deviation in Kospi = 18%
    - Standard Deviation in Korean government Bond = 12%
    - Additional country risk premium for Korea = 0.80% \times \frac{18}{12} = 1.20\%

VI. And it is not just emerging market companies that are exposed to this risk.

- If we treat country risk as a separate risk factor and allow firms to have different exposures to country risk (perhaps based upon the proportion of their revenues come from non-domestic sales)

\[
E(\text{Return}) = \text{Riskfree Rate} + \beta \text{ (US premium)} + \lambda \text{ (Country ERP)}
\]

- The easiest and most accessible data is on revenues. Most companies break their revenues down by region. One simplistic solution would be to do the following:

\[
\lambda = \frac{\% \text{ of revenues domestically}_{\text{firm}}}{\% \text{ of revenues domestically}_{\text{avg firm}}}
\]

- Consider, for instance, the fact that Hyundai Heavy got about 20% of its revenues from Korea and that the typical Korean company gets about 80% of its revenues from Korea. The lambda for Hyundai Heavy is as follow

  - \( \lambda_{\text{Hyundai, Korea}} = \frac{20\%}{80\%} = 0.25 \)

- There are two implications

  - A company’s risk exposure is determined by where it does business and not by where it is located
  - Firms might be able to actively manage their country risk exposures
VII. Discount rates can (and often should) change over time…

- The inputs into the cost of capital - the cost of equity (beta), the cost of debt (default risk) and the debt ratio - can change over time. For younger firms, they should change over time.
- At the minimum, they should change when you get to your terminal year to inputs that better reflect a mature firm.
VIII. Growth has to be earned (not endowed or estimated)

Expected Growth

- Net Income
  - Retention Ratio = 1 - Dividends/Net Income
  - Return on Equity = Net Income/Book Value of Equity

- Operating Income
  - Reinvestment Rate = (Net Cap Ex + Chg in WC/EBIT(1-t))
  - Return on Capital = EBIT(1-t)/Book Value of Capital

- ROC = EBIT (1 - tax rate) / Book Value of Equity + Book value of debt - Cash

Adjust EBIT for:
- a. Extraordinary or one-time expenses or income
- b. Operating leases and R&D
- c. Cyclicality in earnings (Normalize)
- d. Acquisition Debris (Goodwill amortization etc.)

Use a marginal tax rate to be safe. A high ROC created by paying low effective taxes is not sustainable.

Adjust book equity for:
- 1. Capitalized R&D
- 2. Acquisition Debris (Goodwill)

Adjust book value of debt for:
- a. Capitalized operating leases

Use end of prior year numbers or average over the year but be consistent in your application
IX. All good things come to an end. And the terminal value is not an ATM...

\[
\text{Terminal Value}_n = \frac{\text{EBIT}_{n+1} (1 \text{ - tax rate}) (1 \text{- Reinvestment Rate})}{\text{Cost of capital - Expected growth rate}}
\]

- This tax rate locks in forever. Does it make sense to use an effective tax rate?
- Are you reinvesting enough to sustain your stable growth rate? Check Reinv Rate = \( g / \text{ROC} \)
- This is a mature company. It’s cost of capital should reflect that.
- This growth rate should be less than the nominal growth rate of the economy.

In which of these companies is cash most likely to trade at face value, at a discount and at a premium?
Cash: Discount or Premium?

*Market Value of $1 in cash:*
*Estimates obtained by regressing Enterprise Value against Cash Balances*
2. Dealing with Holdings in Other firms

Holdings in other firms can be categorized into

- **Minority passive holdings**, in which case only the dividend from the holdings is shown in the balance sheet
- **Minority active holdings**, in which case the share of equity income is shown in the income statements
- **Majority active holdings**, in which case the financial statements are consolidated.

We tend to be sloppy in practice in dealing with cross holdings. After valuing the operating assets of a firm, using consolidated statements, it is common to add on the balance sheet value of minority holdings (which are in book value terms) and subtract out the minority interests (again in book value terms), representing the portion of the consolidated company that does not belong to the parent company.
In a perfect world, we would strip the parent company from its subsidiaries and value each one separately. The value of the combined firm will be
- Value of parent company + Proportion of value of each subsidiary

To do this right, you will need to be provided detailed information on each subsidiary to estimated cash flows and discount rates.
Two compromise solutions…

- **The market value solution**: When the subsidiaries are publicly traded, you could use their traded market capitalizations to estimate the values of the cross holdings. You do risk carrying into your valuation any mistakes that the market may be making in valuation.

- **The relative value solution**: When there are too many cross holdings to value separately or when there is insufficient information provided on cross holdings, you can convert the book values of holdings that you have on the balance sheet (for both minority holdings and minority interests in majority holdings) by using the average price to book value ratio of the sector in which the subsidiaries operate.
# Hyundai’s Cross Holdings

<td>88.20</td>
<td>1.10</td>
</tr>
</tbody>
</table>

**Value of Cross holdings**: 3937.07
3. Other Assets that have not been counted yet..

- **Unutilized assets:** If you have assets or property that are not being utilized (vacant land, for example), you have not valued it yet. You can assess a market value for these assets and add them on to the value of the firm.

- **Overfunded pension plans:** If you have a defined benefit plan and your assets exceed your expected liabilities, you could consider the over funding with two caveats:
  - Collective bargaining agreements may prevent you from laying claim to these excess assets.
  - There are tax consequences. Often, withdrawals from pension plans get taxed at much higher rates.

Do not double count an asset. If you count the income from an asset in your cashflows, you cannot count the market value of the asset in your value.
### 4. A Discount for Complexity: An Experiment

**Complexity Score =** 51.5
Hyundai: An Enigma wrapped in a Mystery
Dealing with Complexity

In Discounted Cashflow Valuation

- **The Aggressive Analyst**: Trust the firm to tell the truth and value the firm based upon the firm’s statements about their value.
- **The Conservative Analyst**: Don’t value what you cannot see.
- **The Compromise**: Adjust the value for complexity
  - Adjust cash flows for complexity
  - Adjust the discount rate for complexity
  - Adjust the expected growth rate/length of growth period
  - Value the firm and then discount value for complexity

In relative valuation

In a relative valuation, you may be able to assess the price that the market is charging for complexity:

With the hundred largest market cap firms, for instance:

\[ PBV = 0.65 + 15.31 \text{ROE} - 0.55 \beta + 3.04 \text{Expected growth rate} - 0.003 \times \text{Pages in 10K} \]
5. The Value of Synergy

Synergy is created when two firms are combined and can be either financial or operating.

Operating Synergy accrues to the combined firm as:

- **Strategic Advantages**
  - Higher returns on new investments
  - Higher ROC
  - Higher Growth Rate

- **More new Investments**
- **More sustainable excess returns**
- **Longer Growth Period**

Financial Synergy:

- **Economies of Scale**
- **Cost Savings in current operations**
- **Higher Margin**
- **Higher Base-year EBIT**

- **Tax Benefits**
  - Lower taxes on earnings due to:
    - Higher depreciation
    - Operating loss carryforwards

- **Added Debt Capacity**
- **Higher debt ratio and lower cost of capital**

- **Diversification?**
  - May reduce cost of equity for private or closely held firm
Valuing Synergy

(1) the firms involved in the merger are **valued independently**, by discounting expected cash flows to each firm at the weighted average cost of capital for that firm.

(2) the value of the combined firm, with no synergy, is obtained by adding the values obtained for each firm in the first step.

(3) The effects of synergy are built into expected growth rates and cashflows, and the combined firm is re-valued with synergy.

Value of Synergy = Value of the combined firm, with synergy - Value of the combined firm, without synergy
## Valuing Synergy: P&G + Gillette

<table>
<thead>
<tr>

<tr>
<td>Value of Equity</td>
<td>$221,292</td>
<td>$59,878</td>
<td>$281,170</td>
<td>$298,355</td>
</tr>
</tbody>
</table>
5. Brand name, great management, superb product …Are we short changing the intangibles?

- There is often a temptation to add on premiums for intangibles. Among them are
  - Brand name
  - Great management
  - Loyal workforce
    - Technological prowess
- There are two potential dangers:
  - For some assets, the value may already be in your value and adding a premium will be double counting.
  - For other assets, the value may be ignored but incorporating it will not be easy.
## Categorizing Intangibles

<table>
<thead>
<tr>
<th></th>
<th>Independent and Cash flow generating intangibles</th>
<th>Not independent and cash flow generating to the firm</th>
<th>No cash flows now but potential for cashflows in future</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Examples</strong></td>
<td>Copyrights, trademarks, licenses, franchises, professional practices (medical, dental)</td>
<td>Brand names, Quality and Morale of work force, Technological expertise, Corporate reputation</td>
<td>Undeveloped patents, operating or financial flexibility (to expand into new products/markets or abandon existing ones)</td>
</tr>
</tbody>
</table>
| **Valuation approach**    | Estimate expected cashflows from the product or service and discount back at appropriate discount rate. | • Compare DCF value of firm with intangible with firm without (if you can find one)  
• Assume that all excess returns of firm are due to intangible.  
• Compare multiples at which firm trades to sector averages. | Option valuation  
• Value the undeveloped patent as an option to develop the underlying product.  
• Value expansion options as call options  
• Value abandonment options as put options. |
| **Challenges**            | • Life is usually finite and terminal value may be small.  
• Cashflows and value may be person dependent (for professional practices) | With multiple intangibles (brand name and reputation for service), it becomes difficult to break down individual components. | • Need exclusivity.  
• Difficult to replicate and arbitrage (making option pricing models dicey) |

</tbody>
</table>
6. Be circumspect about defining debt for cost of capital purposes…

- **General Rule**: Debt generally has the following characteristics:
  - Commitment to make fixed payments in the future
  - The fixed payments are tax deductible
  - Failure to make the payments can lead to either default or loss of control of the firm to the party to whom payments are due.

- Defined as such, debt should include
  - All interest bearing liabilities, short term as well as long term
  - All leases, operating as well as capital

- Debt should not include
  - Accounts payable or supplier credit
But should consider other potential liabilities when getting to equity value…

- If you have under funded pension fund or health care plans, you should consider the under funding at this stage in getting to the value of equity.
  - If you do so, you should not double count by also including a cash flow line item reflecting cash you would need to set aside to meet the unfunded obligation.
  - You should not be counting these items as debt in your cost of capital calculations….

- If you have contingent liabilities - for example, a potential liability from a lawsuit that has not been decided - you should consider the expected value of these contingent liabilities
  - Value of contingent liability = Probability that the liability will occur * Expected value of liability
7. The Value of Control

The value of the control premium that will be paid to acquire a block of equity will depend upon two factors -

- **Probability that control of firm will change**: This refers to the probability that incumbent management will be replaced. This can be either through acquisition or through existing stockholders exercising their muscle.

- **Value of Gaining Control of the Company**: The value of gaining control of a company arises from two sources - the increase in value that can be wrought by changes in the way the company is managed and run, and the side benefits and perquisites of being in control.

\[
\text{Value of Gaining Control} = \text{Present Value (Value of Company with change in control - Value of company without change in control)} + \text{Side Benefits of Control}
\]
Revenues
* Operating Margin

On June 1, 2008
Hyundai Heavy traded at 350,000 Won/share.
Implications of the Value of Control

- If the value of a firm run optimally is significantly higher than the value of the firm with the status quo (or incumbent management), you can write the value that you should be willing to pay as:

  Value of control = Value of firm optimally run - Value of firm with status quo

  Value of control at Hyundai Heavy = 401,000 Won per share – 362,000 Won per share
  = 39,000 Won per share

- Implications:
  - In an acquisition, this is the most that you would be willing to pay as a premium (assuming no other synergy)
  - As a stockholder, you will be willing to pay a value between 362 and 401 Wn, depending upon your views on whether control will change.
  - If there are voting and non-voting shares, the difference in prices between the two should reflect the value of control.
8. Distress and the Going Concern Assumption

- Traditional valuation techniques are built on the assumption of a going concern, i.e., a firm that has continuing operations and there is no significant threat to these operations.
  - In discounted cashflow valuation, this going concern assumption finds its place most prominently in the terminal value calculation, which usually is based upon an infinite life and ever-growing cashflows.
  - In relative valuation, this going concern assumption often shows up implicitly because a firm is valued based upon how other firms - most of which are healthy - are priced by the market today.
- When there is a significant likelihood that a firm will not survive the immediate future (next few years), traditional valuation models may yield an over-optimistic estimate of value.

Las Vegas Sands
February 2009
Trading @ $4.25
The Distress Factor

In February 2009, LVS was rated B+ by S&P. Historically, 28.25% of B+ rated bonds default within 10 years. LVS has a 6.375% bond, maturing in February 2015 (7 years), trading at $529. If we discount the expected cash flows on the bond at the riskfree rate, we can back out the probability of distress from the bond price:

$$529 = \sum_{t=1}^{10} \frac{63.75(1 - p_{\text{Distress}})^t}{(1.03)^t} + \frac{1000(1 - p_{\text{Distress}})^7}{(1.03)^7}$$

Solving for the probability of bankruptcy, we get:

$$\pi_{\text{Distress}} = \text{Annual probability of default} = 13.54\%$$

- Cumulative probability of surviving 10 years = $(1 - .1354)^{10} = 23.34\%$
- Cumulative probability of distress over 10 years = $1 - .2334 = .7666$ or 76.66%

If LVS is becomes distressed:
- Expected distress sale proceeds = $2,769 million < Face value of debt
- Expected equity value/share = $0.00
- Expected value per share = $8.12 (1 - .7666) + $0/.00 (.2334) = $1.92
9. Equity to Employees: Effect on Value

In recent years, firms have turned to giving employees (and especially top managers) equity option packages as part of compensation. These options are usually:
- Long term
- At-the-money when issued
- On volatile stocks

Are they worth money? And if yes, who is paying for them?

Two key issues with employee options:
- How do options granted in the past affect equity value per share today?
- How do expected future option grants affect equity value today?
Equity Options and Value

- **Options outstanding**
  - Step 1: List all options outstanding, with maturity, exercise price and vesting status.
  - Step 2: Value the options, taking into accounting dilution, vesting and early exercise considerations.
  - Step 3: Subtract from the value of equity and divide by the actual number of shares outstanding (not diluted or partially diluted).

- **Expected future option and restricted stock issues**
  - Step 1: Forecast value of options that will be granted each year as percent of revenues that year. (As firm gets larger, this should decrease).
  - Step 2: Treat as operating expense and reduce operating income and cash flows.
  - Step 3: Take present value of cashflows to value operations or equity.
10. Analyzing the Effect of Illiquidity on Value

- Investments which are less liquid should trade for less than otherwise similar investments which are more liquid.
- The size of the illiquidity discount should vary across firms and also across time. The conventional practice of relying upon studies of restricted stocks or IPOs will fail sooner rather than later.
  - Restricted stock studies are based upon small samples of troubled firms
  - The discounts observed in IPO studies are too large for these to be arms length transactions. They just do not make sense.
Illiquidity Discounts from Bid-Ask Spreads

- Using data from the end of 2000, for instance, we regressed the bid-ask spread against annual revenues, a dummy variable for positive earnings (DERN: 0 if negative and 1 if positive), cash as a percent of firm value and trading volume.

\[
\text{Spread} = 0.145 - 0.0022 \ln (\text{Annual Revenues}) - 0.015 \text{(DERN)} - 0.016 \text{(Cash/Firm Value)} - 0.11 \text{($ \text{Monthly trading volume/Firm Value}$)}
\]

- We could substitute in the revenues of Kristin Kandy ($5 million), the fact that it has positive earnings and the cash as a percent of revenues held by the firm (8%):

\[
\text{Spread} = 0.145 - 0.0022 \ln (5) - 0.015 (1) - 0.016 (0.08) - 0.11 (0) = .12.52\%
\]

- Based on this approach, we would estimate an illiquidity discount of 12.52% for Kristin Kandy.
Relative Valuation

Aswath Damodaran
Relative valuation is pervasive...

- Most asset valuations are relative.
- Most equity valuations on Wall Street are relative valuations.
  - Almost 85% of equity research reports are based upon a multiple and comparables.
  - More than 50% of all acquisition valuations are based upon multiples
  - Rules of thumb based on multiples are not only common but are often the basis for final valuation judgments.
- While there are more discounted cashflow valuations in consulting and corporate finance, they are often relative valuations masquerading as discounted cash flow valuations.
  - The objective in many discounted cashflow valuations is to back into a number that has been obtained by using a multiple.
  - The terminal value in a significant number of discounted cashflow valuations is estimated using a multiple.
The Reasons for the allure…

“If you think I’m crazy, you should see the guy who lives across the hall”
*Jerry Seinfeld talking about Kramer in a Seinfeld episode*

“A little inaccuracy sometimes saves tons of explanation”
H.H. Munro

“If you are going to screw up, make sure that you have lots of company”
Ex-portfolio manager
The Four Steps to Deconstructing Multiples

- Define the multiple
  - In use, the same multiple can be defined in different ways by different users. When comparing and using multiples, estimated by someone else, it is critical that we understand how the multiples have been estimated.

- Describe the multiple
  - Too many people who use a multiple have no idea what its cross sectional distribution is. If you do not know what the cross sectional distribution of a multiple is, it is difficult to look at a number and pass judgment on whether it is too high or low.

- Analyze the multiple
  - It is critical that we understand the fundamentals that drive each multiple, and the nature of the relationship between the multiple and each variable.

- Apply the multiple
  - Defining the comparable universe and controlling for differences is far more difficult in practice than it is in theory.
Definitional Tests

- Is the multiple consistently defined?
  - Proposition 1: Both the value (the numerator) and the standardizing variable (the denominator) should be to the same claimholders in the firm. In other words, the value of equity should be divided by equity earnings or equity book value, and firm value should be divided by firm earnings or book value.

- Is the multiple uniformly estimated?
  - The variables used in defining the multiple should be estimated uniformly across assets in the “comparable firm” list.
  - If earnings-based multiples are used, the accounting rules to measure earnings should be applied consistently across assets. The same rule applies with book-value based multiples.
Example 1: Price Earnings Ratio: Definition

PE = Market Price per Share / Earnings per Share

- There are a number of variants on the basic PE ratio in use. They are based upon how the price and the earnings are defined.
- Price: is usually the current price
  is sometimes the average price for the year
- EPS: earnings per share in most recent financial year
  earnings per share in trailing 12 months (Trailing PE)
  forecasted earnings per share next year (Forward PE)
  forecasted earnings per share in future year
Example 2: Enterprise Value /EBITDA Multiple

- The enterprise value to EBITDA multiple is obtained by netting cash out against debt to arrive at enterprise value and dividing by EBITDA.

\[
\frac{\text{Enterprise Value}}{\text{EBITDA}} = \frac{\text{Market Value of Equity} + \text{Market Value of Debt} - \text{Cash}}{\text{Earnings before Interest, Taxes and Depreciation}}
\]

- Why do we net out cash from firm value?
- What happens if a firm has cross holdings which are categorized as:
  - Minority interests?
  - Majority active interests?
Descriptive Tests

- What is the average and standard deviation for this multiple, across the universe (market)?
- What is the median for this multiple?
  - The median for this multiple is often a more reliable comparison point.
- How large are the outliers to the distribution, and how do we deal with the outliers?
  - Throwing out the outliers may seem like an obvious solution, but if the outliers all lie on one side of the distribution (they usually are large positive numbers), this can lead to a biased estimate.
- Are there cases where the multiple cannot be estimated? Will ignoring these cases lead to a biased estimate of the multiple?
- How has this multiple changed over time?
Looking at the distribution of PE ratios…

PE ratios across markets
Simplistic rules almost always break down…
The PEG<1 = Cheap test?
And 6 times EBITDA may not be cheap…

![EV Multiples - US in January 2009](chart.png)
Analytical Tests

- What are the fundamentals that determine and drive these multiples?
  - Proposition 2: Embedded in every multiple are all of the variables that drive every discounted cash flow valuation - growth, risk and cash flow patterns.
  - In fact, using a simple discounted cash flow model and basic algebra should yield the fundamentals that drive a multiple.

- How do changes in these fundamentals change the multiple?
  - The relationship between a fundamental (like growth) and a multiple (such as PE) is seldom linear. For example, if firm A has twice the growth rate of firm B, it will generally not trade at twice its PE ratio.
  - Proposition 3: It is impossible to properly compare firms on a multiple, if we do not know the nature of the relationship between fundamentals and the multiple.
PE Ratio: Understanding the Fundamentals

- To understand the fundamentals, start with a basic equity discounted cash flow model.
- With the dividend discount model,
  \[ P_0 = \frac{DPS_1}{r - g_n} \]

  - Dividing both sides by the current earnings per share,
    \[ \frac{P_0}{EPS_0} = \frac{Payout \text{ Ratio} \times (1 + g_n)}{r - g_n} \]

  - If this had been a FCFE Model,
    \[ P_0 = \frac{FCFE_1}{r - g_n} \]
    \[ \frac{P_0}{EPS_0} = \frac{(FCFE/Earnings) \times (1 + g_n)}{r - g_n} \]
The Determinants of Multiples...

Value of Stock = DPS \(\frac{1}{(k_e - g)}\)

- **PE** = Payout Ratio \(\frac{1+g}{1+g}/(r-g)\)
  - **PE** = f(g, payout, risk)
- **PEG** = Payout ratio \(\frac{1+g}{g(r-g)}\)
  - **PEG** = f(g, payout, risk)
- **PBV** = ROE (Payout ratio) \(\frac{1+g}{(1+g)}/(r-g)\)
  - **PBV** = f(ROE, payout, g, risk)
- **PS** = Net Margin (Payout ratio) \(\frac{1+g}{(1+g)}/(r-g)\)
  - **PS** = f(Net Mgn, payout, g, risk)

**Equity Multiples**

**Firm Multiples**

- **V/FCFF** = f(g, WACC)
- **V/EBIT(1-t)** = f(g, RIR, WACC)
- **V/EBIT** = f(g, RIR, WACC, t)
- **VS** = Oper Margin \(\frac{1+g}{(1+g)}(1-RIR)/(WACC-g)\)

Value of Firm = FCFF \(\frac{1}{(WACC - g)}\)
Application Tests

- Given the firm that we are valuing, what is a “comparable” firm?
  - While traditional analysis is built on the premise that firms in the same sector are comparable firms, valuation theory would suggest that a comparable firm is one which is similar to the one being analyzed in terms of fundamentals.
  - Proposition 4: There is no reason why a firm cannot be compared with another firm in a very different business, if the two firms have the same risk, growth and cash flow characteristics.

- Given the comparable firms, how do we adjust for differences across firms on the fundamentals?
  - Proposition 5: It is impossible to find an exactly identical firm to the one you are valuing.
An Example: Comparing PE Ratios across a Sector: PE

</tbody>
</table>
Regressing PE ratios against growth, we get

- \( PE = 14.86 + 0.85 \) (Expected growth rate) \( R^2 = 49\% \)
- Plugging in Amgen’s expected growth rate of 15\%, we get
  - \( PE = 14.86 + 0.85 \times 15 = 27.61 \)

At 16 times earnings, Amgen seems to be significantly undervalued by almost 40\% relative to the rest of the pharmaceutical sector.
Comparisons to the entire market: Why not?

- In contrast to the 'comparable firm' approach, the information in the entire cross-section of firms can be used to predict PE ratios.
- The simplest way of summarizing this information is with a multiple regression, with the PE ratio as the dependent variable, and proxies for risk, growth and payout forming the independent variables.
PE Ratio: Standard Regression for US stocks - January 2009

a. Dependent Variable: Current PE
b. Weighted Least Squares Regression – Weighted by Market Cap
Amgen valued relative to the market

- Plugging in Amgen’s numbers into the January 2008 market regression:
  - Expected growth rate = 15%
  - Beta = 0.85
  - Payout ratio = 0%
  - Predicted PE = 10.645 + 1.176 (15) - 2.621 (0.85) = 26.06

- Again, at 16 times earnings, Amgen seems to be significantly undervalued, relative to how the market is pricing all other stocks.
Choosing Between the Multiples

As presented in this section, there are dozens of multiples that can be potentially used to value an individual firm.

In addition, relative valuation can be relative to a sector (or comparable firms) or to the entire market (using the regressions, for instance)

Since there can be only one final estimate of value, there are three choices at this stage:

• Use a simple average of the valuations obtained using a number of different multiples
• Use a weighted average of the valuations obtained using a number of different multiples
• Choose one of the multiples and base your valuation on that multiple
Picking one Multiple

- This is usually the best way to approach this issue. While a range of values can be obtained from a number of multiples, the “best estimate” value is obtained using one multiple.

- The multiple that is used can be chosen in one of two ways:
  - Use the multiple that best fits your objective. Thus, if you want the company to be undervalued, you pick the multiple that yields the highest value.
  - Use the multiple that has the highest R-squared in the sector when regressed against fundamentals. Thus, if you have tried PE, PBV, PS, etc. and run regressions of these multiples against fundamentals, use the multiple that works best at explaining differences across firms in that sector.
  - Use the multiple that seems to make the most sense for that sector, given how value is measured and created.

Real Options: Fact and Fantasy

Aswath Damodaran
In the last few years, there are some who have argued that discounted cashflow valuations under valued some companies and that a real option premium should be tacked on to DCF valuations. To understand its moorings, compare the two trees below:

A bad investment………………….. Becomes a good one..

1. Learn at relatively low cost
2. Make better decisions based on learning
Three Basic Questions

- When is there a real option embedded in a decision or an asset?
- When does that real option have significant economic value?
- Can that value be estimated using an option pricing model?
When is there an option embedded in an action?

- An option provides the holder with the **right** to buy or sell a specified quantity of an underlying asset at a fixed price (called a strike price or an exercise price) at or before the expiration date of the option.
- There has to be a **clearly defined underlying asset** whose value changes over time in unpredictable ways.
- The **payoffs** on this asset (real option) have to be **contingent** on a specified event occurring within a finite period.
Example 1: Product Patent as an Option

- PV of Cash Flows from Project
  - Initial Investment in Project
    - Project has negative NPV in this section
    - Project's NPV turns positive in this section
Example 2: Expansion of existing project as an option

PV of Cash Flows from Expansion

Additional Investment to Expand

Firm will not expand in this section

Expansion becomes attractive in this section

Present Value of Expected Cash Flows on Expansion
When does the option have significant economic value?

- For an option to have significant economic value, there has to be a restriction on competition in the event of the contingency. In a perfectly competitive product market, no contingency, no matter how positive, will generate positive net present value.
- At the limit, real options are most valuable when you have exclusivity - you and only you can take advantage of the contingency. They become less valuable as the barriers to competition become less steep.
Exclusivity: Putting Real Options to the Test

- **Product Options: Patent on a drug**
  - Patents restrict competitors from developing similar products
  - Patents do not restrict competitors from developing other products to treat the same disease.

- **Growth Options: Expansion into a new product or market**
  - Barriers may range from strong (exclusive licenses granted by the government - as in telecom businesses) to weaker (brand name, knowledge of the market) to weakest (first mover).
Determinants of option value

- Variables Relating to Underlying Asset
  - Value of Underlying Asset; as this value increases, the right to buy at a fixed price (calls) will become more valuable and the right to sell at a fixed price (puts) will become less valuable.
  - Variance in that value; as the variance increases, both calls and puts will become more valuable because all options have limited downside and depend upon price volatility for upside.
  - Expected dividends on the asset, which are likely to reduce the price appreciation component of the asset, reducing the value of calls and increasing the value of puts.

- Variables Relating to Option
  - Strike Price of Options; the right to buy (sell) at a fixed price becomes more (less) valuable at a lower price.
  - Life of the Option; both calls and puts benefit from a longer life.

- Level of Interest Rates; as rates increase, the right to buy (sell) at a fixed price in the future becomes more (less) valuable.
The Building Blocks for Option Pricing Models: Arbitrage and Replication

- The objective in creating a replicating portfolio is to use a combination of riskfree borrowing/lending and the underlying asset to create the same cashflows as the option being valued.
  - Call = Borrowing + Buying $\Delta$ of the Underlying Stock
  - Put = Selling Short $\Delta$ on Underlying Asset + Lending
  - The number of shares bought or sold is called the **option delta**.
- The principles of arbitrage then apply, and the value of the option has to be equal to the value of the replicating portfolio.
When can you use option pricing models to value real options?

- The notion of a replicating portfolio that drives option pricing models makes them most suited for valuing real options where
  - The underlying asset is traded - this yield not only observable prices and volatility as inputs to option pricing models but allows for the possibility of creating replicating portfolios
  - An active marketplace exists for the option itself.
  - The cost of exercising the option is known with some degree of certainty.

- When option pricing models are used to value real assets, we have to accept the fact that
  - The value estimates that emerge will be far more imprecise.
  - The value can deviate much more dramatically from market price because of the difficulty of arbitrage.
Biogen, a bio-technology firm, has a patent on Avonex, a drug to treat multiple sclerosis, for the next 17 years, and it plans to produce and sell the drug by itself. The key inputs on the drug are as follows:

- PV of Cash Flows from Introducing the Drug Now = $S = $3.422 billion
- PV of Cost of Developing Drug for Commercial Use = $K = $2.875 billion
- Patent Life = $t = 17$ years
- Riskless Rate = $r = 6.7\%$ (17-year T.Bond rate)
- Variance in Expected Present Values = $\sigma^2 = 0.224$ (Industry average firm variance for bio-tech firms)
- Expected Cost of Delay = $y = 1/17 = 5.89\%$
- $d_1 = 1.1362$, $N(d_1) = 0.8720$
- $d_2 = -0.8512$, $N(d_2) = 0.2076$

Call Value = $3,422 \exp(-0.0589)(17)(0.8720) - 2,875 \exp(-0.067)(17)(0.2076) = $907 million
One final example: Equity as a Liquidation Option

Net Payoff on Equity

Face Value of Debt

Value of firm
Application to valuation: A simple example

- Assume that you have a firm whose assets are currently valued at $100 million and that the standard deviation in this asset value is 40%.
- Further, assume that the face value of debt is $80 million (It is zero coupon debt with 10 years left to maturity).
- If the ten-year treasury bond rate is 10%,
  - how much is the equity worth?
  - What should the interest rate on debt be?
Valuing Equity as a Call Option

Inputs to option pricing model

- Value of the underlying asset = \( S = \) Value of the firm = $100 million
- Exercise price = \( K = \) Face Value of outstanding debt = $80 million
- Life of the option = \( t = \) Life of zero-coupon debt = 10 years
- Variance in the value of the underlying asset = \( \sigma^2 = \) Variance in firm value = 0.16
- Riskless rate = \( r = \) Treasury bond rate corresponding to option life = 10%

Based upon these inputs, the Black-Scholes model provides the following value for the call:

- \( d_1 = 1.5994 \quad \text{N}(d_1) = 0.9451 \)
- \( d_2 = 0.3345 \quad \text{N}(d_2) = 0.6310 \)

Value of the call = \( 100 \times (0.9451) - 80 \times \exp^{-0.10 \times 10} \times (0.6310) = $75.94 \text{ million} \)

Value of the outstanding debt = \( $100 - $75.94 = $24.06 \text{ million} \)

Interest rate on debt = \( (\frac{$80}{$24.06})^{1/10} - 1 = 12.77\% \)
The Effect of Catastrophic Drops in Value

- Assume now that a catastrophe wipes out half the value of this firm (the value drops to $50 million), while the face value of the debt remains at $80 million. Consider the new inputs into the equity valuation:
  - Value of the underlying asset = \( S = \) Value of the firm = $50 million
  - Exercise price = \( K = \) Face Value of outstanding debt = $80 million
  - Life of the option = \( t = \) Life of zero-coupon debt = 10 years
  - Variance in the value of the underlying asset = \( \sigma^2 = \) Variance in firm value = 0.16
  - Riskless rate = \( r = \) Treasury bond rate corresponding to option life = 10%

- Based upon these inputs, the Black-Scholes model provides the following value for the call:
  - \( d_1 = 1.0515 \) \( N(d_1) = 0.8534 \)
  - \( d_2 = -0.2135 \) \( N(d_2) = 0.4155 \)
  - Value of the call (Equity) = 50 (0.8534) - 80 \( \exp^{(-0.10)(10)} \) (0.4155) = $30.44 million
  - Value of the debt = $50 - $30.44 = $19.56 million
Equity value persists ..
Back to Lemmings...
